

FINAL - Courtney “Root” Phillips

So for my final assignment, I wanted to relate it to my own degree. I am the Lighting Design MFA candidate which obviously requires an understanding of light and how it interacts with subjects. I wanted to make a simulator to simulate how different angles of light can affect how a subject is lit. My favorite angle to utilize in my own work is back light as I love the outline that it creates around a subject. However, there are still different types of backlight! Back diag., back side, back top, up back, etc. So, I made a simulator just to simply illustrate the effect that light has on an object. This can be helpful for my own field to visualize how a plot might function but, artists with more physical mediums like paint can also utilize it to help understand how to illustrate light in their work.

I linked the X value of the light source to mouseX so viewers can control the light source.

Also, there is a lot of variables that are unnecessary because I was making it much more complicated than I needed to when I was planning this all out so just ignore all that, haha!
